SAMPLING YEARBOOK VOLUME 2

for the year 1957

Edited by Ronald S. Keir

Issued from the Headquarters of the Commission
Halifax, N.S., Canada
1959

PREFACE

At the Sixth Annual Meeting of the International Commission for the Northwest Atlantic Fisheries in June 1956 it was recommended that

> "For each species sampled each country should report to the Secretariat the sizes, ages, weights, and sexes of the fish sampled, by place and time of capture. The Commission should publish these statistics."

This number of the Sampling Yearbook, the second in the series, is considerably larger than the first, due partly to the increased quantity of samples reported by the member countries, but also to the inclusion of two papers which summarise results from earlier sampling.

The Sampling Yearbook has been prepared and edited by the Commission Biologist-Statistician, Mr. Ronald S. Keir. The printing has been done in the Secretariat.

The Commission greatly appreciates the co-operation it has received from the many contributors to this volume.

GUIDE TO TABLES

Explanation of Guide

The numbers in the guide are page numbers. For a length frequency reference the page number alone is given. For an age frequency the page number is followed by A. For an age frequency with mean size at each age, the page number of followed by A'. For an age-length key or frequency the page number is followed by K. For a weight-length table the page number is followed by W. For discard experiments the page number is followed by D.

Where '(year)' follows a page number the data referred to are not given by month or quarter, but as totals for the year.

NK indicates subdivision not known.

INTRODUCTION

by Ronald S. Keir

The Sampling Yearbook summarises annually the data on lengths, ages and weights of the cod, haddock, redfish, and some other species of interest to the Commission, which have been collected to further the investigations on the fisheries and fish stocks of the Northwest Atlantic. This volume includes tables of all the length frequencies of samples taken in 1957 from commercial landings or catches and, for some countries, of the catches of research vessels. Age frequency data have also been reported by several countries. Tables I, II, and III summarise the extent of the 1957 sampling for cod, haddock and redfish, respectively, and Table IV summarises by countries the sampling reported in this volume.

Samples are taken either on shore from the commercial landings or at sea from the catches of commercial or research vessels. Where the commercial vessel catch is sampled at sea, samples may be taken before or after discarding of the small, unmarketable fish. In sampling the landings, samples are usually taken from each of the size categories in which the fish are landed, and the overall length frequency estimated by pooling the samples after weighting by the quantity of fish landed in each size category. Where samples are taken at sea no weighting factors are used, and samples are simply added together to obtain the average length frequency of the catch. As sampling practices vary among countries, some further "Notes on the Sampling Data" are given on pages 17 to 21.

Because of the size and complexity of the fisheries in the Convention Area and because of the large number of countries and variety of fishing gear involved, the amount of sampling required to estimate the length and age frequencies of the catches or landings is very much larger than that now carried out, and most sampling programmes will need to be extended and intensified.

It was the intention of the Commission that the data incorporated in the Sampling Yearbook should be readily intercomparable. To this end the Commission proposed that the fork length recorded to the nearest centimetre be adopted as the standard measure. It further recommended that length measurements should be reported by 3-centimetre groups for the cod and by 2-centimetre groups for the haddock. Only two methods of measuring fish are now in common use in the Convention Area: the one is the standard measure noted above, which is extensively used in Subareas 2, 3, 4, and 5; and the other is the total length measured to the centimetre below, which is used by several of the countries

fishing in Subarea 1. The latter method of measuring differs from the standard in two ways: measuring to the total length gives a greater length, which is compensated to some extent by measuring to the centimetre below, which gives a lesser length. Because of the very small differences involved and the limited data available to establish conversion factors, no conversions to standard measure have been made. Length frequencies are usually given in parts per thousand; however, in the case of the United States haddock sampling in Subarea 5, where the sampling is intensive, the estimated numbers landed are given.

The Commission has not yet defined a standard method for the presentation of age data. Where sufficient data were reported, an age-length frequency table is published; otherwise, the data are published an an age frequency with mean length at each age (if known).

Data are occasionally reported separately for the sexes and are so published.

Length-weight data are reported as mean weight at each length.

The amount of sampling on which the length frequencies and other tables are based is generally small and the tables should therefore be used with caution. In many cases, sampling from different depth zones, and possibly even different stocks, in a subdivision are pooled. The number of significant figures in the tables is frequently greater than justified by the data. Similarly, the mean weight of the fish and the estimated number of fish landed, etc., are often given to a larger number of significant figures than justified by the data or by the conversion factors used; for example, the conversion factor of 1.2 used to convert from gutted weight to round, fresh weight may be considered to introduce an error of approximately ± 5 per cent.

Weights are always recorded in metric tons round, fresh, except where otherwise noted. The conversion factors used are the same as those used in the ICNAF Statistical Bulletins (see Vol. 5, 1955, page 13). The most commonly used are:-

1.2 for cod and haddock, gutted, head on
3.0 for cod and haddock, green salted, landed in Europe
2.7 for cod and haddock, green salted, landed in North America or Greenland

Two series of measurements taken to measure discarding practices in cod fisheries are reported in this volume of the Sampling Yearbook. The series from Canada (Table 2) is based on measurements of samples of the total catch

taken at sea, and later of the landings from the same trip, the difference between the two being attributed to discarding. Ten trips were studied. The British data (Table 35), on the other hand, consist of direct estimates made at sea of the quantity and length frequency of the discards, and of measurements made on shore of the landings from the same trip. Only one trip was studied. Both sets of data indicate 50 per cent discarding points of about 46 cm for cod.

Two reviews, summarising earlier data, have been prepared for this volume of the Sampling Yearbook. The first, "Length-Weight Tables for Northwest Atlantic Haddock" by John R. Clark and Eli L. Dietsch, summarises a considerable body of data on the haddock of the southern part of the Convention Area. The second, on "Cod Samples from 1956" by Erik M. Poulsen, reviews the material given in the Sampling Yearbook Volume 1.

TABLE I. COD - 1957 SAMPLING REPORTED

NOTES ON THE SAMPLING DATA

Canada (Maritimes and Quebec) — Reported by D.N. Fitzgerald and W.R. Martin

Commercial landings of groundfish in the provinces of Nova Scotia, New Brunswick and Prince Edward Island have been continuously sampled for size and age composition since 1945. Sampling emphasis has been placed on landings by offshore vessels at the largest groundfish ports, but has also included sampling from the inshore fleets. The sampling data on cod, haddock, redfish, plaice, and witch lengths in 1957 have been reported to the Commission. (See summary in Table IV on page 22.

Landings are normally culled by market categories. Cod are divided into Large (Steak) and Medium (Market) sizes at about 10 pounds fresh, gutted weight. Small (Scrod) cod and haddock are mainly less than 2-1/2 pounds gutted weight. Small round haddock are sometimes landed in a separate market category. These market categories are sampled approximately in proportion to the relative numbers of each in a trip landing. When the final weighout is available, the length frequency of the landings is determined by applying weighting factors to each category. The length frequencies of the sexes are not given separately.

Fork length measurements were recorded to the nearest centimetre for each fish. These measurements are presented by 3-centimetre groups for cod and 2-centimetre groups for haddock. Mesh size is recorded as the approximate inside stretched wet used measurement of an average codend mesh. Hook size is given by number, No. 17 or 6/0 being the smallest commercial groundfish hook, and No. 12 being the large hook used on baited handlines.

Samples were also reported from observations made to determine the proportions of fish discarded at sea by otter trawlers when using various codend mesh sizes. The catches and landings of ten trips were studied. These data show a marked reduction in the quantity of fish caught but discarded when a mesh size of 4-1/2 inches or greater is used rather than a mesh size of about 3-1/4 inches.

Canada (Newfoundland) — Reported by A.M. Fleming and M.E. Prouse

Length frequencies based on sampling of the commercial landings of cod and haddock in 1957 have been reported. The numbers and the extent of the sampling are summarised in Table IV on page 22.

Length measurements were made of the fork length and recorded to the nearest centimetre. Sampling was carried out on shore. The total weight of each sample was obtained, together with the total weight of the species landed from the trip sampled. By means of the weighting factor determined from these data each sample frequency was raised to give the actual numbers of each size in the landings sampled. These raised frequencies were then pooled to give length frequencies by quarters (January-March, etc.), type of gear and subdivision, and then compiled in 3-centimetre groups (0-2 cm, etc.).

The 4-inch mesh size recorded for traps is to be considered a minimum.

Denmark — Reported by Paul M. Hansen

Samples of cod were taken from the catches of commercial gears (inshore) and from the catches of the R.V. "Dana" and R.V. "Adolf Jensen" (offshore), as summarised in Table IV on page 22. The samples were not pooled. Length measurements were made of the total length (end of tail lobes) and recorded to the nearest centimetre below.

A special series of redfish length samples has been taken at intervals of one to three months from Godthåb and Tunugdliarfik Fjords (since 1952 in the case of Godthåb Fjord). These are of small redfish and permit the study of the growth rate, using Petersen's method, as discussed in the Danish Research Report for 1956, ICNAF Annual Proceedings, Vol. 7. The samples taken from 1952 to 1956 were reported in the Sampling Yearbook, Vol. 1. The samples taken in 1957 are reported in this volume. Measurements were made of the total length and recorded to the centimetre below. These measurements have not been adjusted to the nearest centimetre or to the fork length.

France — Reported by J. Ancellin and C. Nédélec

Samples taken from the trawl catches of the Research Vessel "Président Théodore Tissier" in 1954 in Subdivision 4T are reported. Measurements were made to the total length to the centimetre below and have not been standardised.

Altogether, 2,300 otoliths were collected on this trip of the "Président Théodore Tissier" from several areas of Subareas 3 and 4, but details have so far been reported from only two samples totalling 289 otoliths.

Observations made on French otter trawlers in Subarea 4 in 1958 by J.R. Clark and F.D. McCracken are recorded in Table 16. Measurements were made to the fork length to the nearest centimetre.

Germany — Reported by A. Kotthaus and A. Meyer

Age-length frequencies of the 1957 landings of cod by otter trawlers from Subarea 1 have been reported. Length frequencies of redfish landings for 1955, 1956, 1957, and 1958 from Subarea 1 and for 1958 from Subareas 2 and 3 were reported. The age-length frequencies of the cod catches of the Research Vessel "Anton Dohrn" (using a covered codend) were reported. Length measurements were made of the total length (end of tail lobes) and recorded to the centimetre below. The length frequencies were reported to the Commission by centimetres.

Sampling was carried out on shore at the market. For the cod each of the three size categories landed was sampled separately, and the final length frequency calculated by weighting each length frequency by the quantity landed in the size category from which it was taken and then pooling the frequencies. The cod from the commercial landings were gutted before being measured; the redfish were round, except for a few of the larger ones.

Samples of otoliths were taken, stratified according to length of fish, and the age-length key constructed from this data, together with the length frequencies, was used to estimate the age distribution of the landing.

Iceland — Reported by Jón Jónsson

Cod age frequencies and age at first spawning (from otoliths) for 1957 with mean length at each age, based on the sampling of the otter trawler landings from Subarea 1, were reported. Length measurements were made of the total length recorded to the nearest centimetre, and compiled in 3-centimetre groups (0-2 cm, etc.).

Norway — Reported by Birger Rasmussen

The age-length frequency of samples of the commercial handline catch in Holsteinsborg Deep was reported.

Measurements were made of the fork length to the nearest centimetre.

Portugal — Reported by Mario J. Ruivo

Sampling at sea of the cod catches (before discarding undersized fish) of the Portuguese otter trawlers and dory vessels has been carried out in 1957 in Subareas 1, 2, 3, and 4. Length frequencies, age frequencies (based on otoliths), and the mean size at each age by sexes were included in the data reported.

Length measurements were made of the fork length recorded to the nearest centimetre and were compiled in 5-centimetre groups (0-4 cm, etc.). Samples were not weighted by the quantity caught; when taken on the same fishing bank at the same time they were generally pooled.

Samples from cod catches taken in 1956 from Subarea 4 are also included in this volume. Note that the 1956 samples were taken after discarding undersized fish.

Observations made on a Portuguese otter trawler in Subarea 4 in 1958 by J.R. Clark and F.D. McCracken are recorded in Table 16.

Spain — Reported by Alfonso Rojo

Length frequencies of the cod, haddock and pollock catches of Spanish otter trawlers collected at sea for the year 1957 were reported, together with age-length keys. Samples were taken from the commercial catch before discarding.

Length measurements were made of the fork length recorded to the nearest centimetre. Cod ages were based on otoliths. Samples were not weighted according to the quantity caught. They were added together by month/subdivisions and the combined frequencies printed.

Union of Soviet Socialist Republics — Reported by Ul. Marti

The age frequency and the length frequency of redfish catches were reported. Samples were taken at sea before discarding from the catches of commercial otter trawlers.

United Kingdom — Reported by C.E. Lucas and R.S. Wimpenny

The length composition of the cod landings of the United Kingdom otter trawlers from Subarea 1 was reported. Measurements were made of the total length to the centimetre below. To determine the length composition of the landings, samples were taken from each of the size categories into which the landings were divided. The length frequencies so obtained were then pooled, after weighting by the quantity of fish in the category from which they were taken.

Observations were also made at sea on one trip of an otter trawler to measure discarding practices, and these data were reported to the Commission.

United States

Reported by J.R. Clark, G.M. Clarke, E.L. Dietsch, F. Dreyer, G.F. Kelly, K.E. Murray, and J.P. Wise

The age-length composition of the United States landings of haddock for 1956 and 1957 and the length composition of the landings of cod and redfish are included in this volume. All measurements were made of the fork length to the nearest centimetre.

Compilation of Data

(a) Cod: Subarea 5, Otter Trawlers

Each length frequency sample was weighted by the weighout of the landing from which it was obtained (by market category for large, market, scrod; by total cod for mixed). The resulting length frequencies of sample landings were totalled and weighted by total United States cod landings for otter trawlers by quarters. These numbers were in turn combined into length frequencies for total United States otter trawl cod landings for each quarter.

(b) Haddock

The length frequency samples for each month by market category were pooled and the resulting frequency weighted by the total quantity of each category landed from each unit area. The weighted numbers of fish of each category were then pooled to obtain the total length frequency for haddock for each month for each subdivision. The age frequencies were determined from the length frequencies and age-length keys constructed from subsamples of the original samples. Ages were determined from the scales. The resulting age-length frequency expresses the total removals of haddock from the subdivision for the particular month.

Haddock biostatistical records are maintained by the "haddock year": namely, February 1st to January 31st of the following year. The haddock's birthday is taken as February 1st.

(c) Redfish

Samples were taken from the commercial catches and were pooled without weighting.

TABLE IV. SUMMARY BY COUNTRIES OF SAMPLING REPORTED

Country and Species	Gear	Area	No. of Samples	No. Fish Measured	Observations	
CANADA (M)	1957

LENGTH-WEIGHT TABLES FOR NORTHWEST ATLANTIC HADDOCK

by John R. Clark and Eli L. Dietsch

The collection of biostatistical information on the United States haddock fishery has been carried out continuously since 1931. The data are used principally to study the nature and extent of fluctuations in abundance and the effect of fishing on the stocks. In order to evaluate the importance of the various factors affecting the abundance of haddock it is necessary to determine the total removals by the fishery in terms of the weight and numbers of the various ages and sizes represented in the catches. The determination of removals requires the use of length-weight relationships to calculate the weight of the length samples of the landings, so that the proportion of the total landings which they represent can be determined.

An extensive series of length-weight observations has been collected since 1931 to establish the relationships required for our studies. Some length-weight data for haddock have previously been published by Herrington (1935) and Schuck (1951). It is the purpose of this study to present the complete collection of data in a form most useful to persons engaged in studying the haddock fishery of ICNAF Subareas 4 and 5.

Studies of growth rate, age and size composition, meristic attributes, and tag return records have shown that the haddock of Subareas 4 and 5 do not form one homogeneous population, but are divided into many population units. Preliminary analysis of our data revealed differences in length-weight among these units.

For this reason we allotted our data for analysis to five major population divisions, conforming to Subdivisions 4W, 4X, 5Y, 5Z east, and 5Z west. These divisions are shown in Figure 1. The individual samples are listed in Tables 1 to 4. The lengths used are those recommended by the Commission: i.e., they represent the distance between the tip of the snout and the shortest ray of the caudal fin and are assigned to the mid-point of each centimetre interval.

Haddock are typically landed in the "dressed" condition: gutted from December to March, and both gutted and gilled from April to November. It is, therefore, the dressed weight that we are concerned with in our study and our tables show the values in these terms. An average conversion factor of 1.17 may be used to convert dressed to whole ("round") weights. The factor is 1.14 for gutted haddock and 1.20 for gutted and gilled haddock.

As preliminary inspection of the data revealed seasonal changes in the length-weight relations, the data were grouped by months for analysis. The cyclic nature of the variation in weights is illustrated in Figure 2 for Subdivisions 4W and 5Z west. This cyclic pattern is consistent throughout our data for the larger sizes and becomes more pronounced with increasing length. The haddock with which we are concerned are nearly all mature at 45 centimetres; no significant pattern occurs below this length.

These findings agree with results obtained by Russell (1914) for haddock of the North Sea. Russell's suggestion that the variations in weight may be related to the sexual and feeding cycles of haddock is confirmed by our data. The height of spawning occurs in March in Subdivisions 5Y and 5Z, in April in Subdivision 4X, and in April to May in Subdivision 4W. The period of lowest weight coincides with the spawning period, occurring between March and May. Studies on haddock feeding (Wigley, 1956) have shown that food consumption of Georges Bank haddock is lowest in February to April and increases thereafter, reaching a peak in June. Vladykov (1954) discovered a similar relation in Nova Scotian offshore haddock: namely, a low point in February and a peak in July.

As data are not available throughout the year for any area, the weights for months not represented in the samples were estimated. The estimated weights were read from curves such as those shown in Figure 2, which were fitted to points for the available samples. These points were established from regression analysis of fish weight against logarithm of fish length. The weights were estimated to the nearest tenth of a pound for haddock larger than 40 centimetres and to the nearest hundredth of a pound for haddock less than 40 centimetres.

The monthly length-weight tables thus derived are presented in Tables 5 to 8 for Subdivisions 4W, 4X, 5Z east, and 5Z west. The division of Subdivision 5Z into east and west components was done to coincide with observed differences in the stocks of the two areas, which are now being studied separately. Insufficient samples were available to derive a table for Subdivision 5Y. Comparison of the two 5Y samples available with those of the other areas indicates that the tables constructed for 5Z west can be used for 5Y. This usage is substantiated by many studies which have shown that the haddock of Subdivisions 5Y and 5Z west are similar and may be considered as units of the same subpopulation (e.g., Needler, 1930).

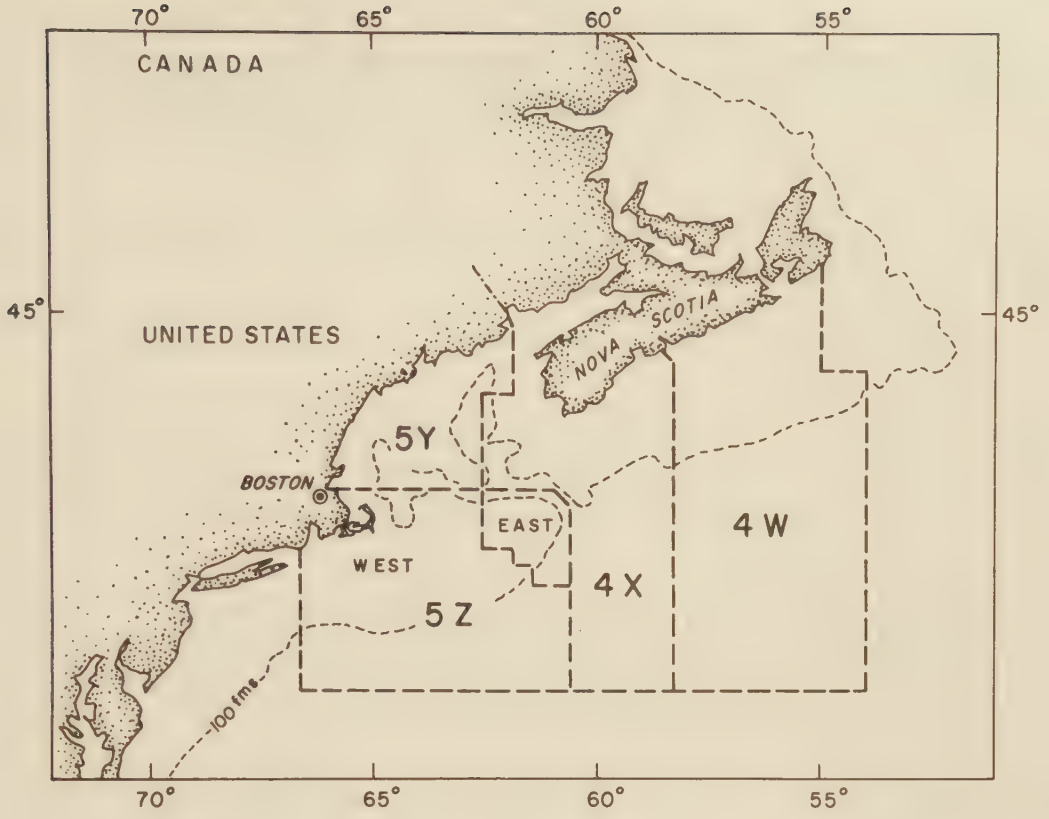

Figure 1. Areas from which length-weight samples were collected.

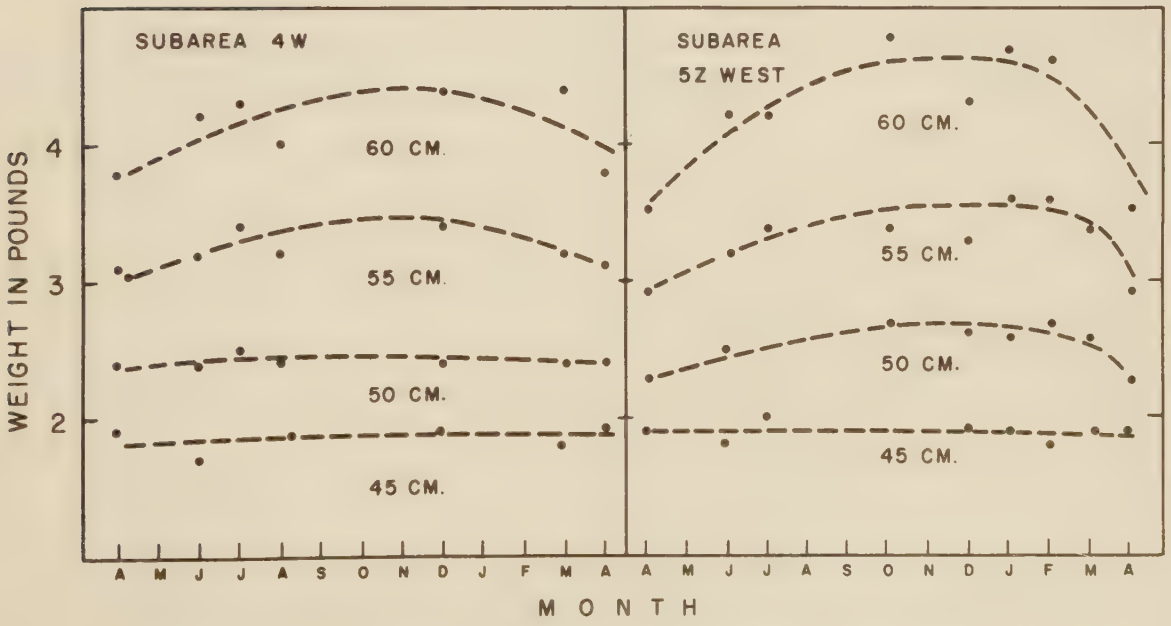

Figure 2. Seasonal changes in the weight of haddock of different lengths from Subdivisions 4W and 5Z west.

COD SAMPLES FROM 1956

by Erik M. Poulsen

This paper is based on length measurements of cod (Gadus callarias L.) for 1956 published in the ICNAF Sampling Yearbook Vol. 1[1].

The following countries reported data from one or more of the Commission's five subareas:-

Country \ Subarea	1	2	3	4	5	No. of Subareas	Samples taken before or after discarding unmarketable fish
Canada	-	-	+	+	-	2	after
Denmark	+	-	-	-	-	1	before
Germany	+	-	-	-	-	1	after
Norway	+	-	-	-	-	1	before
Portugal	+	+	-	+	-	3	after
Spain	-	-	+	-	-	1	before
U.K.	+	-	-	-	-	1	after
U.S.A.	-	-	-	-	+	1	after
No. of countries	5	1	2	2	1	...	...

An 'a' in the text or figures indicates that sampling was done after discard of unmarketable fish, a 'b' indicates sampling before such discard.

Five countries reported samples from Subarea 1, two from Subareas 3 and 4, and one from each of Subareas 2 and 5.

The numbers of cod measured and included in the above samples are as follows:-

	No. of Cod Measured
Subarea 1	15,698
Subarea 2	2,309
Subarea 3	27,641
Subarea 4	14,963
Subarea 5	3,855
Total	64,466

1) The Portuguese samples for Subarea 4 were not available when the Sampling Yearbook was printed. They are here cited from ICNAF Document Serial No. 600, Appendix VIII.

The differences in measurements - caused by the fact that for Subarea 1 some countries measure to the nearest centimetre, others to the nearest centimetre below, some countries to the end of the lobes of the caudal fin, others to the middle of its hind margin - are so small compared to the size of the cod as to be termed negligible; they are not considered at all in the following. All samples measured in Subareas 2, 3, 4, and 5 were measured to the nearest centimetre and to the fork length.

3. Summary by Subareas, Subdivisions

Figure 1 shows the length distribution in parts per thousand by subareas of all samples from otter trawl fishery, disregarding countries, discards or no discards, etc.

The measurements, in 3-centimetre groups, range from <35 cm to >96 cm. In the smallest and largest 3-centimetre groups a very few cod belonging to smaller or larger centimetre groups are included. In the few cases where a considerable number were included in these two end groups, the mean length of the sample was calculated before this contraction.

The mean lengths of the cod sampled from the otter trawl fishery in the different subareas vary from 57.5 cm in Subarea 2 to 66.5 cm in Subarea 4. When samples from all gears are pooled the following average lengths are found: Subarea 1 - 70.2 cm; Subarea 2 - 57.5 cm; Subarea 3 - 64.2 cm; Subarea 4 - 67.8 cm; and Subarea 5 - 60.8 cm. The increases in average length for Subareas 1, 3 and 4 are due to the addition of samples from the various hook fisheries.

In 1956 the following quantities of cod (metric tons, round fresh) were landed from the five subareas:-

Subarea 1	321,245 tons	33.9 per cent
Subarea 2	34,283 tons	3.6 per cent
Subarea 3	381,705 tons	40.2 per cent
Subarea 4	198,076 tons	20.9 per cent
Subarea 5	13,246 tons	1.4 per cent
Total	948,555 tons	100.0 per cent

Thus 95 per cent of the cod landed from the Convention Area come from Subareas 1, 3 and 4, and only 5 per cent from Subareas 2 and 5.

The cod landed from Subareas 2 and 5 are smaller than those landed from

the other subareas: 57.5 and 60.8 cm respectively. The difference in average weight would be much more marked; for example, although the cod from Subarea 2 are 82 per cent as long as those from Subarea 1, they are less than 55 per cent as heavy.

The mean lengths for the other three subareas, yielding in their total 95 per cent of the cod landed from the Convention Area, are fairly close to one another:-

	All Fisheries			Otter Trawl Only
	Mean Length	Length	Weight	Mean Length
Subarea 1	70.2 cm	100 per cent	100 per cent	66.2 cm
Subarea 4	67.8 cm	97 per cent	90 per cent	66.5 cm
Subarea 3	64.2 cm	91 per cent	75 per cent	61.3 cm

The difference in length between the subareas amounts to only 6 cm, or less than 9 per cent. This great conformity as to mean length of cod taken from the various regions of the Convention Area does not necessarily give proof of a correspondingly great similarity between the stocks as far as length is concerned. It may well be caused by the selection of the fishing fleets in order to land the sizes of cod preferred by the markets. This selection of the fleet is effected in the main by the following steps: 1) construction of gear (mesh and hook sizes), 2) selection of fishing area (avoiding areas with too many small cod), and 3) culling after capture. Each of these steps alienates the picture the samples give us from that of the stock of fish in the sea, approaching it to that of the demands of the market.

The samples show that there must be a pronounced conformity of the demands of the markets with respect to the sizes of the fish, and that the size compositions of the various stocks permit the fishing fleets, by proper choice of gear, fishing grounds and culling, to provide fish of a size acceptable to the markets. This may well make it advisable to consider the introduction of the same regulations of the cod fisheries through the whole of the Convention Area, which would facilitate the implementation and the control of regulations.

Although the mean sizes of cod taken in the various subareas are fairly close to one another, a considerable variation can be found in the form of the length-distribution curves. This variation must be caused by a somewhat different size- (and age-) distribution within the stocks themselves.

The peaks of the curves (Figure 1) for Subareas 2 and 5 are higher than those for the other subareas and show a steeper decline to both sides. This may well be due to the fact that for each of these two subareas only one fishery has been sampled; viz. in Subarea 2, the Portuguese trawl fishery, and in Subarea 5,

the United States trawl fishery. The distribution curves for the other subareas are based on samples from several countries.

The curve for Subarea 1 - although not quite so compressed as those for Subareas 2 and 5 - has its peak somewhat higher (off 135‰) than the curves for Subareas 3 and 4 (off 100‰ and 105‰ respectively). As the number of countries reporting samples is higher in Subarea 1 than in Subareas 3 and 4, it can be assumed that the varying form of the curves indicated different size-compositions of the stocks of these subareas.

The Portuguese samples, which include samples taken by otter trawl in both Subarea 1 and Subarea 4, make it possible to verify this assumption by direct comparison of samples taken by the same fleet in the two subareas. Figure 2 presents the length distributions of Portuguese otter trawl samples from Subdivisions 1B, 1C and 1D (May-September), and from Subdivisions 4R, 4S, 4T, and 4V (March-April), all samples taken after discarding. It is apparent that the mean lengths for these two groups of samples from widely separated regions are very close to one another: 66.1 cm (Subarea 1) and 66.8 cm (Subarea 4); this coincides well with the facts that in both cases the same type of gear, the same mesh size and the same fishing methods were used, and that the landings were intended for the same markets. However, the form of the curves is quite different. That for Subarea 1 is strongly compressed around a high peak off 155‰, with an equally strong decline to both sides (the peak being at the same length group as the mean, 66 cm). The curve for Subarea 4, on the other hand, is very much flattened; its peak reaches only 101‰. The decline from the peak (at 57 cm, that is, considerably below the mean length of 66.8 cm) is rather fast to the left (smaller sizes) and very slow to the right (larger sizes). As a different selectivity of the gear or a different culling is unlikely, the reasons for the different forms of the curves must be found in the stocks themselves. The main bulk of the cod in Subarea 1 must be composed of only a few year-classes with their mean sizes close to the peak, in Subarea 4 of a larger number of year-classes.

The reports on the Portuguese samples also include data on age. Figure 2 shows the age-distribution of samples from Subareas 1 and 4. The samples from Subarea 1 include far fewer older fish than those from Subarea 4. The proportion of cod of age 10 and more is 311‰ in Subarea 4, against only 64‰ in Subarea 1. The peculiar flattened upper part of the curve for Subarea 1 gets its explanation from the two rich ages, 6 and 9, making up the bulk of the cod, with two poor ages, 7 and 8, between them.

Figure 3 illustrates the regional length-distribution by subdivision; it

includes all samples, irrespective of gear and country.

In Subarea 1 the cod taken from Subdivisions 1B (the most northern of the subdivisions sampled) and 1F (the most southern) are somewhat smaller (mean lengths 65 and 67 cm) than the cod from the more central fishing banks, Subdivisions 1C, 1D and 1E (71-73 cm).

For Subarea 3 the fish are, on the whole, a little smaller than for Subarea 1. The largest cod (mean lengths 66-68 cm) come from Subdivisions 3O and 3P, i.e. the most southwestern subdivisions bordering Subarea 4. The cod from Subdivision 3L (northern part of the Grand Bank) are a little smaller (64 cm). Those from Subdivision 3N (the southeastern part of the Bank) are much smaller, only 52.5 cm. However, this latter figure is hardly comparable with the others; it represents a Spanish sample measured before discarding, whereas all the other samples from this subarea are taken after discarding. In considering the figures it ought to be noted that all samples were made before the present trawl regulations became effective. The curves for the four subdivisions of Subarea 3 are generally more flattened - including a larger number of bigger fish - than those for Subarea 1.

All curves for the Subarea 4 subdivisions are very much flattened, indicating a considerable intermixture of larger fish; this is especially so for the subdivisions off the Nova Scotian east and south coasts (Subdivisions 4V, 4W and 4X). The especially low average length for the samples from Subdivision 4V is due to a Canadian offshore trawl sample in August, which included mainly small cod from 45-59 cm, and no cod at all larger than 70 cm; this sample can hardly be regarded as typical of the subdivision. Portuguese samples from the same subdivision in March and April show the usual heavy intermixture of larger cod.

2. Summary by Countries

Figure 4 shows the samples by countries and for each country, by subareas. The largest cod taken in the Convention Area are those taken by Norway, with an average length of 73.2 cm; the measurements were made before discarding. In evaluating this high average it should be noted that most of the Norwegian samples come from line fisheries; only two samples are from purse seines and there are none from the trawl fishery, which generally yields smaller cod than the line fishery. Next in size come the Danish samples, with an average length of 69.9 cm. These samples also are taken before discarding, and all of them are from hook fisheries by jig and long lines. The Danish and Norwegian samples are all from Subarea 1. Close in size to the Danish samples

are those of Portugal from Subareas 1 and 4 (mean sizes 68 and 67 cm). Far smaller are the Portuguese otter trawl samples from Subarea 2, with a mean length of 57.5 cm. The Portuguese samples from Subarea 1 include otter trawl as well as dory catches, those from Subarea 4 only otter trawl catches; all samples were taken after discarding. The U.K. samples, all from Subdivision 1F, the southern part of Subarea 1, and taken by otter trawl, after discarding, show a mean of 67 cm, very close to the mean for the Portuguese samples. The Canadian samples from Subareas 3 and 4, taken after discarding and from the landings of a variety of gears, have a mean size of 66-67 cm, just below the British samples. The German samples, all from the landings of otter trawlers, after discarding, and from Subdivisions 1D and 1F, are again a little smaller, with a mean of 65 cm. Considerably smaller, with a mean of 60.6 cm, are the United States samples, all from otter trawler landings in Subarea 5 and taken after discarding. The smallest-sized cod from the 1956 samples are those from the Spanish trawl fishery in Subdivision 3N, taken before discarding and having a mean length of only 52.3 cm.

Disregarding the fisheries in Subareas 2 and 5 where, compared to the other subareas, only insignificant fisheries for cod are carried out, and the Spanish sample from Subdivision 3N, which is exceptionally small-sized, we find - as when considering the summary by subareas - a marked uniformity as to sizes of cod taken from the various main cod fishing regions of the Convention Area. The range of variation of mean sizes within the various countries is only from 65.3 to 73.2 cm.

A comparison of these curves by countries sampling after discarding and before discarding does not show any pronounced difference in the form of the curves. It is true that the curves for U.K. and U.S.A. present a steep decline on the left side of the curve, but for Canada, and to a certain degree also for Portugal - two other countries sampling after discard - no such steep decline is present. Further, the Danish and Spanish samples, taken before discarding, show a decline to the left almost as steep as U.K. and U.S.A. Only the Norwegian samples, taken before discarding, show a more gradual decline to the left of the peak. Unfortunately, for 1956 no sampling of the same catches before and after discarding was reported. It is to be hoped that countries will find opportunities for sampling the same fisheries, or even catches, both before and after discarding[1].

3. Summary by Gear

To summarise the material for a comparison of length-distribution for

[1] Canada and the U.K. reported such data for 1957.

the various types of gear used, the following classification of fisheries by gears is used:-

1. Otter trawl fisheries
2. Hook fisheries from dory vessels
3. Other hook fisheries (long lines, hand lines, jig)
4. Purse seine fisheries
5. Cod trap fisheries

A summary of the length-distribution by gear is presented in Figure 5 panel A, where samples are pooled by gears, disregarding countries, regions, discard or no discard. It is apparent that the largest cod are those taken by the dory vessel hook fisheries (mean length 70.6 cm). Next, and very close, come the samples from other hook fisheries: long lines, hand lines, jig, for which samples the mean length is 68.5 cm. As the samples from the dory fisheries were all taken after discarding (by Canada and Portugal), whereas the samples from the other hook fisheries (except for the Canadian samples) were taken before discarding (Danish and Norwegian samples), it is probable that the cod taken by other hook fisheries are not smaller than those taken by the dory vessels.

The cod from the trawl fisheries are considerably smaller than the cod from the hook fisheries; they have a mean size of only 62.4 cm, i.e. about 8 cm lower than the cod taken with hooks.

Two small samples from purse seine catches in Subarea 1 (not shown in the figure) exhibit the same high average length (70.2 cm) as the hook fishery samples.

The samples from the Canadian fishery with cod traps in Subarea 3, however, include smaller fish than any of the other sample-groups, averaging only 58.1 cm.

Figure 5, B, C and D, shows a comparison of samples from otter trawls, dory fishing and other hook fisheries for Subareas 1, 3 and 4 separately. The cod taken by the otter trawlers are somewhat smaller than the cod taken by the dory vessels or by other hook fisheries, the difference being from 4 to 10 cm. It is to be noted that the cod sampled from Canadian dory vessels in Subarea 4 are considerably larger - 75.8 cm - than those from Subarea 3 - 68.7 cm - although they are taken with the same size hook (#16).

Panels E and F show a comparison of length-distribution of samples

from the Norwegian fishery in Subdivision 1B with hand lines and with floating long lines, the latter fishery yielding the larger fish, and from the Danish fishery in Subdivision 1D with long lines and with jig; only a small difference was found in the latter case.

Panel G shows a comparison of Canadian long line samples, offshore and inshore, in Subdivision 4X; the two curves and their mean lengths are very similar.

Figure 6, A and B, shows length variation of otter trawl samples by different countries within the same subareas. Germany, Portugal and U.K. all trawl for cod in Subarea 1. The form of the length-distribution curves and the mean lengths are very much alike; the mean length only varies between 65.3 and 67.1 cm, i.e. less than 2 cm.

A similar small variation is found in Subarea 4, where Canadian samples give a mean of 65.2 cm and Portuguese samples, 66.8 cm. The trend of the two curves for this subarea is much the same: rather flat curves with the peak well below the mean length, meaning a fairly great intermixture of large fish.

Figure 6C compares Portuguese dory vessel samples from the three subdivisions, 1B, 1C and 1D. It is apparent that there is a marked difference among the three subdivisions. The smallest cod are from 1B (most northern), considerably larger are the cod from 1C, and the cod from the most southern of these subdivisions, 1D, is still larger; the difference in mean length between 1B and 1D amounts to 6 cm.

Samples from other hook fisheries (long lines, hand lines, jig) are reported by Canada from Subareas 3 and 4 (Figure 6, E and F), and by Denmark and Norway from Subarea 1 (Figure 6D).

The largest cod taken by this hook fishery come from Subarea 1 (71.5 cm). The cod from Subarea 4 are only a little smaller (70.0 cm); those from Subarea 3 are considerably smaller (only 65.0 cm). It must here be noted that the samples from Subarea 1 are taken before discarding, those from Subareas 3 and 4 after discarding; therefore, the actual difference in size can be assumed to be still greater than the figures show.

Summary

1. The samples with the highest mean lengths come from Subareas 1 and 4,

farther below is Subarea 3 and then Subarea 5. The smallest cod are those from Subarea 2 (Figure 1).

2. The variation in mean lengths of the samples from Subareas 1, 3 and 4, which yield 95 per cent of the cod landings from the Convention Area, is small: the mean lengths are 70.2, 67.8 and 64.2 respectively.

3. The form of the length curves differs, however, considerably: a compressed, rather high-peaked curve for Subarea 1, a flattened, low-peaked curve for Subarea 4, and in a lesser degree for Subarea 3. This means a difference in length composition of the stocks on the fishing grounds: more smaller and more larger cod in Subareas 4 (and 3) than in Subarea 1 (Figures 1-6).

4. In Subarea 1 the largest cod come from the central fishing banks, Subdivisions 1C, 1D and 1E (71-73 cm); the cod from the most northern (1B) and most southern (1F) subdivisions are smaller (65 and 67 cm) (Figure 3 and Figure 6C).

5. In Subarea 3 the largest cod (66-68 cm) come from the southwestern subdivisions (3O and 3P), bordering Subarea 4. In Subdivisions 3L and 3N - Grand Bank - the cod are a little smaller (64 cm). In a single sample from Subdivision 3N, from the southeastern Grand Bank, the cod were much smaller (52.2 cm) (Figure 3).

6. In Subarea 4 the largest cod (74.5 cm) come from the southwest, with a very considerable number of big, old cod in the samples. Subdivisions 4X and 4V - bordering Subareas 5 and 3 - present lower means (65.1 and 61.0 cm). In the Gulf of St. Lawrence larger cod are found in the western and southern parts (Subdivisions 4S - 70.6 cm and 4T - 70.7 cm) than in the eastern part (4R - 63.8 cm) (Figure 3).

7. The samples with the highest average sizes come from Denmark and Norway (Subarea 1 only and hook fishery mainly); next come Canada and Portugal (trawl and hook fisheries); thereafter follow the countries using only trawls (Figure 4).

8. Dory fisheries and other hook fisheries yield the largest cod (70.6 and 68.5 cm respectively); somewhat smaller are the cod from the trawl fisheries (62.4 cm); considerably smaller are those from trap fisheries (58.1 cm) (Figure 5).

9. The fact that trawl-caught cod are on the whole smaller than line-caught cod shows that when regulating the fisheries, the trawl fisheries have to be considered first, as has been the case.

(cont'd.)

Codend mesh size: 160 mm. (new)

1) There were no age nor sex observations on fish of over 86 cm.; hence the 19% over 86 cm. have been distributed evenly between males and females and assumed to be of over 9 years of age. 2) The data for total males and females are given on the previous page.
